

Well Support Clamps

The age of increasing numbers of North Sea wells means their integrity has become compromised over the years. Damage to the casing can cause downward movement of the wellhead into the conductor transferring loads to parts of the wellhead not designed to cope with them.

To meet the specific challenges faced by our customers, we have developed a number of innovative clamps designed to reduce the loads imparted on these areas of the wellhead and prolong the life of such ageing wells.

The main principle is to redistribute the loads to parts of the well that have more strength and can support the well and any equipment rigged up on the well.

Each wellhead support clamp is designed with load calculations verified to prove the design is fit for purpose. The designs allow for well growth and movement during production, as well as providing additional support for extra loads associated with the deployment of drilling/intervention equipment during workovers, interventions and well abandonments.
